#### Abstract

Fourier transform infrared (FTIR) and FT-Raman spectra have been recorded and extensive spectroscopic investigations have been carried out on Sulfamethoxazole (SMX). The structural and spectroscopic data of the molecule in the ground state were calculated by using Density Functional Theory (DFT) using $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ basis set. The vibrational frequencies were calculated and scaled values were compared with experimental FT-IR and FT-Raman spectra. In order to explore the molecular dynamic activity for describing root cause of obtained molecular chemical property, the FT-IR and FT-Raman experimental spectra investigated along with the computational results. The observed and calculated frequencies are found to be in good agreement. The theoretically constructed FT-IR and FT-Raman spectra exactly coincide with experimental one. The first order hyperpolarizability of this novel molecular system and related properties of CFA are calculated using B3LYP/6-311++G(d,p) and HF/6-311++G(d,p) methods on the finite-field approach.

Keywords: Density Functional Theory, Nonlinear optical effects (NLO), Mulliken charge distribution, Sulfamethoxazole, UV-Visible.

## 1. Introduction

Sulfamethoxazole (SMZ or SMX) is an antibiotic. It is used for bacterial infection. It was introduced
to the United States in 1961(Chemla DC and Zyss J et al. 1987) ${ }^{[1]}$. To the best of our knowledge, neither quantum chemical calculation, nor the vibrational spectra sulfamethoxazole have been reported. Therefore, the present investigation was undertaken to study the vibrational spectra of this molecule completely and to identify the various modes with greater wavenumber accuracy. Density Functional Theory (DFT) and Hartree Fock (HF) (French MJ, Inc., 2009) ${ }^{[2]}$ calculations have been performed to support our wavenumber assignments. Hence, in the present work, a detailed vibrational analysis, chemical shifts, HOMOLUMO, Mulliken atomic charge, thermodynamic studies, NMR spectral analysis and UV-Visible spectral analysis has been attempted using DFT/B3LYP and HF methods at $6-311++G(d, p)$ basis set by recording FT-IR and FT-Raman spectra of the compound.

## 2. Experimental Details

Fourier transform infrared spectra of the title compound is measured at the room temperature in the region $4000-400 \mathrm{~cm}^{-1}$ using a BRUKER IFS-66 V FTIR spectrometer (Aiping F, Dongmei, and Zhengyu Z, 2000) ${ }^{[3]}$ at a resolution of $\pm 1 \mathrm{~cm}^{-1}$ equipped with a MCT detector, a KBr beam splitter and globar source. The FT-Raman spectrum of $2,4-$ BDA was recorded on a BRUKER IFS -66 V model interferometer equipped with

International Journal of Advanced Scientific Research and Management, Volume 3 Issue 11, Nov 2018

FRA-106 FT-Raman accessory in the 3500-100 $\mathrm{cm}^{-1}$. Stokes region using the 1064 nm line of a Nd:YAG laser for excitation operating at 200 mW power. The reported wave numbers are believed to be accurate within $\pm 1 \mathrm{~cm}^{-1}$. The UV-visible absorption spectrum of the sample was recorded using a Varion Cary 5E UV-VIS, NIR spectrophotometer in the range $200-400 \mathrm{~nm}$ with high resolution (Moorthy N., et al 2016) ${ }^{[4]}$.

## 3. Computational Details

Calculations of the title compound were carried out with Gaussian09 program using the HF/6-31G (2d,p), B3LYP/6-31G (d,p) and B3LYP/6-311++G(d,p) levels of theory to predict the molecular structure and vibrational wave numbers. Molecular geometry Fig. 1 was fully optimized by Berny's optimization algorithm using redundant internal coordinates (Beck AD, Rev., 1988) ${ }^{[5]}$. Harmonic vibrational wave numbers were calculated using the analytic second derivatives to confirm the convergence to minima of the potential surface. The wave number values computed contain known systematic errors and hence, we have used scaling factors 0.8929 and 0.9613 for HF and DFT methods.

The absence of imaginary wave numbers of the calculated vibrational spectrum confirms that the structure deduced corresponds to minimum energy. The assignments of the calculated wave numbers are aided by the animation option of GAUSSVIEW program, which gives a visual presentation of the vibrational modes. The potential energy distribution (PED) is calculated with the help of GAR2PED software package. The optimized geometrical parameters (B3LYP/6$11++\mathrm{G}(\mathrm{d}, \mathrm{p})$ are given in Table 1.

## 4. Results and Discussion

## Molecular geometry

The geometrical structure along with numbering of atoms of Sulfamethoxazole is obtained from Gaussian 03W and GAUSSVIEW programs are shown in Fig.1. The optimized geometrical parameters of DPA obtained by DFT-B3LYP/6-311++G (d,p) and HF/6-311++G(d,p) levels are listed in Table 1. From the structural data
given in Table 3, it is observed that the various bond lengths are found to be almost same at HF and B3LYP levels.

Fig. 1 Optimized geometric structure of Sulfamethoxazole.

However, the B3LYP/6-31++G (d,p) level of theory, in general slightly over estimates bond lengths but it yields bond angles in excellent agreement with the HF method (Zhao Y, et al.2006) ${ }^{[6]}$. The calculated geometric parameters can be used as origin to calculate the other parameters for the compound. The calculated $\mathrm{C}-\mathrm{C}$ bond lengths of the ring vary from 1.37 to $1.48 \AA$. In this study the $\mathrm{C}-\mathrm{H}$ bond lengths were studied as $1.08 \AA$. The density functional calculation gives almost same bond angles in tested molecule. The dihedral angles of our title molecule show that our tested molecule was planar. In generally the optimized bond length and bond angles are slightly smaller than the experimental values. This is due to the fact that all the theoretical calculations belongs to isolated molecule (Krishnamoorthy. V and Balachandran V, 2006) ${ }^{[7]}$ were done in gaseous state and the experimental results were belongs to molecule is in solid state. . The CN single bond length calculated at $1.279 \AA, 1.3799 \AA$ and double bond length at $1.317 \AA$ which exactly correlates with experimental values at $1.380 \AA, 1.401 \AA$ and $1.292 \AA$ respectively. The calculated S-O bond lengths are $1.4184 \AA$ and $1.426 \AA$ which show moderate agreement with the experimental one at 1.435 and $1.416 \AA$ respectively. The O3-S1-C8-C9 bond angle observed at $157^{\circ}$.

Fig. 2\& 3 Experimental and Theoretical Spectra of FT-Raman and FT-IR.

## 4. Vibrational assignments

### 4.1 Carbon \& Hydrogen (C-H) Vibrations

The existence of one or more aromatic rings in a structure is readily determined from the $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}=\mathrm{C}-\mathrm{C}$ ring related vibrations. The $\mathrm{C}-\mathrm{H}$ stretching occurs above $3000 \mathrm{~cm}^{-1}$ and is typically exhibited as a multiplicity of weak to moderate bands compared with the aliphatic C-H stretch (Saxena R, et al. 2002) ${ }^{[8]}$. In this region the bands are not affected appreciably by the nature of substituent. From Table 2 the observed FT-IR and FT-Raman spectral wavenumbers are assigned to the C - H stretching modes of aromatic group of sulfamethoxazole. The very strong bands in FT-IR at 3096 and $2872 \mathrm{~cm}^{-1}$ in FT-Raman spectra are assigned to $\mathrm{C}-\mathrm{H}$ stretching vibrations in the out of lane vibrations are observed. The observed the same vibrations which also correlated with the experimental values.

### 4.2 Carbon \& Carbon (C-C) Vibrations

This vibrations are appears to be mixed mode as evident from the Table 2 with participation of C-C stretching vibrations. The experimental value for these modes in FT-IR and FT-Raman spectrum indicate an excellent agreement with our calculations.

### 4.3 S-H \& N-H Vibrations

The S-H vibrations are appeared in the frequency range 922,816 in plane bending $\mathrm{N}-\mathrm{H}$ vibrations are appeared in the frequency range 734, 554 out of plane bending.

## 5. Frontier molecular orbital analysis

The Highest Occupied Molecular orbital (HOMO) and the Lowest-lying Unoccupied Molecular Orbital (LUMO) are named as Frontier Molecular Orbitals (FMO) (Silverstein R.M and Webster F.X, et al. 2003) ${ }^{\text {[9] }}$. The FMO is an important role in the optical and electric properties, as well as in quantum chemistry and UV-Visible spectrum. The HOMO represents the ability to donate an electron, LUMO as an electron acceptor represents the ability to obtain an electron. The electronic absorption corresponds to the transition from the ground to the first excited state and is mainly described by one electron excitation from the HOMO to the LUMO. Chemical hardness (g) and softness (s) can be used as harmonizing tools to describe the thermodynamic aspects of chemical reactivity. The Frontier orbital gap helps to characterize the chemical reactivity kinetic stability, chemical reactivity, optical polarizability, chemical hardness, softness of a molecule. The investigations of FT-IR, FT-Raman, UV-Visible, FT-NMR Spectra and Quantum Chemical Computations of Sulfamethoxazole Molecule calculated HOMO and LUMO energy and the energy values of the frontier orbitals by B3LYP/6$311++G(d, p)$ are presented in Table 3. The
ionization potential (I.P) values suggest how tightly an electron is bound within the nuclear attractive field of the systems. It is linearly related with the chemical hardness (g). By using HOMO and LUMO energy values for a molecule, the Ionization potential and chemical hardness of the molecule were calculated using Koopmans' theorem (Perdew J.P et al. 1983) ${ }^{[10]}$ and are given by

$$
\Delta_{x c}=\{I P-E A\}-\left\{\varepsilon_{n+1}(n)-\varepsilon_{n}(n)\right\}
$$

Where IP and EA are the ionization potential and electron affinity, respectively, and $\varepsilon_{\mathrm{n}+1}$ indicates the $m^{\text {th }}$ orbital energy of the $n$-electron system. Perdew and Levy and Casida verified in different ways that HOMO energy is identical to the minus IP, $\varepsilon_{\mathrm{n}}(\mathrm{n})=$ -IP. On the basis of above equation, this implies that LUMO energy corresponds to the minus EA, $\varepsilon_{\mathrm{n}+1}(\mathrm{n})=-E A$. The hardness has been associated with the stability of chemical system. Considering the chemical hardness, large HOMO-LUMO gap means a hard molecule and small HOMO-LUMO gap means a soft molecule. One can also relate the stability of molecule to hardness, which means that the molecule with least HOMO-LUMO gap means, it is more reactive. The hard molecules are not more polarizable than soft ones because they need big energy to excitation 3D plots of the HOMO, LUMO, orbitals computed at the B3LYP/6$311++G(d, p)$ level. The electron affinity can be used in combination with ionization energy to give electronic chemical potential (Krishnakumar V \& John Xavier R, 2003) ${ }^{[11]}$.

$$
\mu=\frac{1}{2}(\varepsilon \mathrm{LUMO}+\varepsilon \mathrm{HOMO})
$$

Chemical $\operatorname{softness}(S)=1 / \eta$ describes the capacity of an atom or group of atoms to receive electrons and is the inverse of the global hardness. The soft molecules are more polarizable than the hard ones because they need small energy to excitation. A molecule with a low energy gap is more polarizable and is generally associated with the high chemical activity and low kinetic stability and is termed soft molecule8. A hard molecule has a large energy gap and a soft molecule has a small energy gap It is shown from the calculations that Sulfamethoxazole
has the least value of global hardness (2.632835ev) and the highest value of global softness $(10.53134 \mathrm{eV})$ is expected to have the highest inhibition efficiency.

The global electrophilicity index ( $\omega$ ) has been defined by Parr et al. (1999) ${ }^{[12]}$ as

$$
\omega=\frac{\mu^{2}}{2 \eta}
$$

From this $\mu \approx-(\mathrm{I}+\mathrm{A}) / 2$ and $\eta \approx(\mathrm{I}-\mathrm{A}) / 2$ are the electronic chemical potential and the chemical hardness respectively, approximated in terms of the vertical ionization potential (I) and electron affinity (A). The electrophilicity is a descriptor of reactivity that allows a quantitative classification of the global electrophilic nature of a molecule with in a relative scale and effectively is the power of a system to 'soak up' electron.

The global electrophilicity index of Sulfamethoxazole is also calculated from the B3LYP 6311++G(d,p) and UV-visible, there values are listed in Table 3.

## 6. NLO Properties

Non-Linear Optical (NLO) (Keresztury G, et al.2002) ${ }^{[13]}$ effects arise from the interactions of electromagnetic fields in various media to produce new fields altered in phase, frequency, amplitude or other propagation characteristics from the incident fields. The first hyper polarizability of this novel molecular system and related properties of Sulfamethoxazole are calculated using DFT/B3LYP method at $6-311 \mathrm{G}++(\mathrm{d}, \mathrm{p})$ basis set based on the finite field approach. NLO is at the forefront of current research because of its importance in providing the key functions of frequency shifting, optical modulation, optical switching, optical logic, and optical memory for the emerging technologies in areas such as telecommunications, signal processing, and optical inter connections.

Table 3: Calculated energies, Chemical hardness, Electro negativity, Chemical potential, Electrophilicity index of Sulfamethoxazole in UV-Visible.

| Parameter | $\begin{gathered} \text { B3LYP } \\ \text { 6311++G } \\ (\mathbf{d}, \mathrm{p}) \end{gathered}$ | UV-Visible | Electrophilicity Charge Transfer (ECT) $\left(\Delta \mathbf{N}_{\text {max }}\right)_{A}-\left(\Delta \mathbf{N}_{\text {max }}\right)_{B}$ |

| Electrophilicity index ( $\omega$ ) | 7.393030 | 9.00291 |  |
| Dipole moment | 5.9161 | 5.9161 |  |

In the presence of an applied electric field, the energy of a system is a function of the electric field. First order hyper polarizability is a third rank tensor that can be described by $3 \times 3 \times 3$ matrices. The 27 components of the 3D matrix can be reduced to 10 components due to the Kleinman symmetry. It can be given in the lower tetrahedral format. It is obvious that the lower part of the $3 \times 3$ x 3 matrices is a tetrahedral. The components of $\beta$ are defined as the coefficients in the Taylor series expansion of the energy in the external electric field.

When the external electric field is weak and homogeneous, this expansion becomes: $E=E_{0^{-}}$ $\mu \alpha F \alpha-1 / 2 \alpha \alpha \beta F \alpha F \beta-1 / 6 \beta \alpha \beta \gamma F \alpha F \beta F \gamma+\ldots$. Where $\mathrm{E}_{0}$ is the energy of the unperturbed molecules, $\mathrm{F} \alpha$ is the field at the origin, $\mu \alpha, \alpha \alpha \beta$ and $\beta \alpha \beta \gamma$ are the components of dipole moment, polarizability and the first order hyperpolarizabilities, respectively. DFT has been extensively used as an effective method to investigate the organic NLO materials.

Polarizability is the property of a species and it is minimum for most stable species and is maximum for least stable species like transition state. The $\alpha$ and $\beta$ values of the Gaussian 05 output are in atomic units (a.u) and these calculated values converted into electrostatic unit (e.s.u) ( $\alpha: 1$ a.u $=$ $0.1482 \times 10^{-24} \mathrm{esu}$; for $\beta$ : 1 a.u $=8.639 \times 10^{-33} \mathrm{esu}$;) and these above polarizability values of Sulfamethoxazole are listed in Table 4. The total
dipole moment (Mohan.J ed al.2001) ${ }^{[14]}$ can be calculated using the following equation.

$$
\mu=\sqrt{ }\left(\mu x^{2}+\mu y^{2}+\mu z^{2}\right)
$$

Table 4: The Electronic Dipole moment (Debye), Polarizability and first hyperpolarizability of Sulfamethoxazole

| Para meter | a.u | Para meter | a.u |
| :---: | :---: | :---: | :---: |
| $\alpha_{x x}$ | -70.7525 | $\beta_{\mathrm{xxx}}$ | -63.7329 |
| $\alpha_{x y}$ | -12.4315 | $\beta_{\text {xxy }}$ | -64.4482 |
| $\alpha_{y y}$ | -108.5586 | $\beta_{\text {xyy }}$ | 17.6783 |
| $\alpha_{x z}$ | -0.4007 | $\beta_{y y y}$ | -56.6573 |
| $\alpha_{y z}$ | -5.4278 | $\beta_{\text {xxz }}$ | -55.0667 |
| $\alpha_{z z}$ | -107.1550 | $\beta_{\mathrm{xyz}}$ | 8.0731 |
| $\alpha_{\text {tot }}$ | 220.635 | $\beta_{y y z}$ | -6.3909 |
| $\Delta \alpha$ | 283.635 | $\beta_{x z z}$ | 7.9455 |
| $\mu_{\mathrm{x}}$ | -0.4932 | $\beta_{y z z}$ | -4.3115 |
| $\mu_{y}$ | -4.2713 | $\beta_{z z z}$ | -5.4213 |
| $\mu_{\text {z }}$ | -3.9574 | $\beta$ tot | 215.2758 |
| $\mu_{\text {tot }}$ | 5.8437 |  |  |

## 7. Conclusion

The FTIR, FT-Raman, UV-Vis spectral measurements have been made for the Sulfamethoxazole molecule. The complete vibrational analysis and first order hyperpolarizability, HOMO and LUMO analysis and thermodynamic properties of the title compound was performed on the basis of DFT and HF calculations at the $6-311++G(d, p)$ basis set. The consistency between the calculated and experimental FTIR and FT-Raman data indicates that the B3LYP and HF methods can generate reliable geometry and related properties of the title compound. The difference between the observed and scaled wave number values of most of the fundamentals is very small. The Mulliken atomic charges and the natural atomic charges obtained are tabulated that gives a proper understanding of the atomic theory. The calculated dipole moment and first order hyperpolarizability results indicate that the title compound is a good candidate of NLO material. The calculated normal-mode vibrational frequencies provide thermodynamic properties by the way of statistical mechanics.
